

The result shows that water quality parameters in Tarapacá River is not so good, especially B, As and Fe. However, information is limited to only this river, supplementary observation on the other rivers was done, as explained in the latter section, for the evaluation of water quality in the whole basin.

### 3.3.3 Supplementary Observation

#### 1) Objective

The purposes of the observation are to measure flow rate and examine water quality in the whole basin for the estimation of available water resources.

#### 2) Location

Observation points are located as follows:

| Location    | Code | Latitude | Longitude |
|-------------|------|----------|-----------|
| 1. Aroma    | AR-1 | 19° 37'  | 69° 31'   |
| 2. Tarapaca | TR-1 | 19° 55'  | 69° 30'   |
| 3. Quipisca | QP-1 | 20° 00'  | 69° 11'   |
| 4. Sagasca  | SG-1 | 20° 11'  | 69° 20'   |

Location of these points are shown in Fig. A, 3.2 and A, 3.3.

#### 3) Observation Method

The measurement was conducted by JICA Study Team & DGA. River conditions during the measurement are shown in Appendix A, 3.3. The items of measurement are as follows;

##### (1) Flow Rate

Flow velocity was measured by a propeller current meter across the river section at a length interval of about 1/10th of the river width. Flow rate was calculated as the product of average velocity times cross sectional area

$$Q = \sum_{i=1}^m V_i \times A_i$$

where Q = flow rate (m<sup>3</sup>/s),  
V = flow velocity (m/s),

A = cross sectional area of the river (m<sup>2</sup>) and  
m = number of sub-cross sections.

## (2) Water Quality

Samples were taken from the checking points and analyzed mostly in the DGA laboratory following the standard method of water quality analysis. However, pH, EC, Temperature, Turbidity and DO were analyzed in situ. Items of the analysis are classified as follows;

- (i) Health Significance : As, Cd, Cr, CN, F, Pb, NO<sub>3</sub>
- (ii) Aesthetic Quality : Al, Cl<sup>-</sup>, Cu, CaCO<sub>3</sub>, Fe, Mn, Na, SO<sub>4</sub>, TDS, Zn, pH
- (iii) Others : HCO<sub>3</sub>, CO<sub>3</sub>, Ca, Mg, K, B, E.C.  
Temperature, Turbidity, DO

## 4) Date of Observation

Observation was carried out on 7<sup>th</sup> - 10<sup>th</sup> October, 1993

## 5) Results of Observation

### (1) Surface Flow Rate

Flow rate at each points is shown in Table A, 3.5.

Flow rate in Tarapacá River, measured by JICA Study Team is found to be lower than average flow rate obtained from DGA's record during October and November, 199\_\_ probably due to the less precipitation in the upstream than usual.

### (2) Water Quality

Results of the examination is shown in Table A, 3.6.

- Aroma is the most contaminated river in the basin in terms of health significance, aesthetic quality and other.
- Sagasca is also a contaminated river in terms of aesthetic quality and other.

- Tarapacá and Quipisca are clean in comparison with Aroma and Sagasca but some items such as B, Ca, Mg, K, etc., are still higher than the standard limit.

| > 350.0             | -                       | -                                    | -  | -                                 |                                       |  |                                |                                      |
|                     |                         | 1,716.30                             | 1,503.62   | 176,989.68                        | 117.71                                | 9,555,408 (m <sup>3</sup> /year)                 | 0.054                          | 2,905                                |

Note : - Average basin rainfall is calculated from Average Annual Precipitation Map (Isohyetal Map) by DGA in 1987

- Flow rate is obtained from monthly data observed by DGA

- Upstream average altitude of the station is obtained by averaging the altitude of the rainfall stations located in the upstream basin of that station

## Chapter IV SURFACE WATER OF SALAR DE HUASCO BASIN

### 4.1 General

Salar de Huasco basin, located in the Region I in northern Chile has a total drainage basin area of 1,712 km<sup>2</sup> and covers the river basin of 1,112 km<sup>2</sup> and residual basin of 600 km<sup>2</sup>. Drainage basin area is shown in Fig. A, 4.1 and Table A, 4.1.

#### 4.1.1 Climate and Precipitation

Information on climate in the basin is obtained from Collacagua weather station at Collacagua village and Salar de Huasco weather station at Vertiente Laguna. Maximum monthly average temperature is in December at 20.3 °C and minimum one is in July at -15.0 °C. Humidity is not observed in the basin.

Precipitation is observed regularly by DGA and Meteorological Department. The stations are shown in Fig. A, 4.2.

Average annual precipitation regionally varies from 150 mm in Huasco lagoon area to 250 mm in the highest mountain areas as shown in Fig. 4.2.

#### 4.1.2 River System

Collacagua River, the main river, flows southwards from the north, meets its tributaries, Batea and Piga, at Pampa Batea and flows down to Salar de Huasco lake, which is a closed lake. Flow model is shown in Fig., A, 4.3.

### 4.2 Surface Flow Rate

#### 4.2.1 Flow Rate at Major Stations

Daily water levels are observed at DGA's observation stations by automatic recorders. Flow rate at each station is generally calculated by the so called "Discharge Rating Curve" or "H-Q Curve" which is a

calibration curve of water level and flow rate. Major observation stations are as follows;

| <u>River</u>      | <u>Location</u> | <u>Observation Period</u> |
|-------------------|-----------------|---------------------------|
| <u>Piga</u>       | Ojos de Agua    | 1947 - 1990               |
|                   | Confluencia     | 1959 - 1967               |
|                   | Collacagua      | 1980 - 1990               |
| <u>Collacagua</u> | Peñablanca      | 1981 - 1990               |

Average, maximum and minimum surface flow rates of these stations in the recorded years are shown in Table A, 4.2. Monthly fluctuation of flow rates throughout the year are shown in Fig. A.4.4 and recorded monthly flow rates are shown in Appendix A, 4.1.

The average flow rates of the above stations are as follows.

| <u>Stations</u> | <u>Average Flow Rate (m<sup>3</sup>/s)</u> |
|-----------------|--|
| Ojos de Agua    | 0.072                                      |
| Confluencia     | 0.023                                      |
| Collacagua      | 0.139                                      |
| Peña Blanca     | 0.197                                      |

The whole surface run-off of the basin finally infiltrates into underground to recharge the groundwater of the basin.

#### 4.2.2 Calculation of Runoff Coefficient

Average yearly rainfall contour map prepared by DGA in 1987, as shown in Fig. A, 4.2, is used to calculate the surface runoff coefficient which in this case is the ratio of the average indigenous flow rate in Collacagua River at Peñablanca, to average annual precipitation in its upstream basin. Runoff coefficient is found to be 0.042 at Peñablanca as shown in Table A, 4.3. This can be interpreted that about 4.2 % of rainfall runs off through Collacagua River as surface flow.

#### 4.3 Surface Water Quality at Major Stations

Water quality is observed by DGA. Water quality samples are taken from the river and analyzed in the laboratory. Observation stations are as follows;

| <u>River</u>      | <u>Location</u> | <u>Observation Period</u> |
|-------------------|-----------------|---------------------------|
| <u>Collacagua</u> | Peñablanca      | 1983 - 1989               |

The items of the analysis are classified as follows;

- (1) Health Significance : As, N-NO<sub>3</sub>, N-NO<sub>2</sub>, N-NH<sub>3</sub>
- (2) Aesthetic Quality : Cl<sup>-</sup>, Cu, Fe, Na, P, SO<sub>4</sub>, pH
- (3) Others : HCO<sub>3</sub>, CO<sub>3</sub>, Ca, Mg, K, B, E.C.

Results of the examination are shown in Table A, 4.4.

Note :  
 - Average basin rainfall is calculated from Average Annual Precipitation Map (Isohyetal Map) by DGA in 1987  
 - Flow rate is obtained from monthly data observed by DGA  
 - Upstream average altitude of the station is obtained by averaging the altitude of the rainfall stations located in the upstream basin of that station

## Chapter V EVALUATION OF RUNOFF IN PAMPA DEL TAMARUGAL AND SALAR DEL HUASCO BASIN

### 5.1 General

In Pampa del Tamarugal Basin, existing data of the surface flow rate are limited to the Tarapacá River. No data is available in the other rivers.

In Salar del Huasco Basin, the surface flow rate has been observed by DGA at Peñablanca of Collacagua River, and at Ojos de Agua, Confluencia and Collacagua of Quebrada Piga River.

However, the Peñablanca station does not catch the whole run-off of its upstream basin. Because some portion of the river flow infiltrates into underground before reaching the station since the station is located on the alluvial deposits. Furthermore, some river water bypasses the station at a flood time.

On the other hand, the drainage areas of the other three (3) stations are so small that it is difficult to directly estimate the total discharge of Collacagua River from the discharge records at the three (3) stations.

Considering the above situations, the surface water run-off of Pampa del Tamarugal and Salar del Huasco is estimated from the rainfall records of the basins.

In the above estimation, the basin average rainfall is to be calculated by weighting the point rainfall records distributed in the basin. In this study, the basin average rainfall was calculated by using the rainfall isohyetal map prepared by DGA in 1987.

### 5.2 Relationship of Rainfall and Run-off Coefficient

The relationship between rainfall and run-off coefficient in the Study Area was obtained from the observed discharge data at the following stations within and near the Study Area.

| River        | Quebrada    | Station               |
|--------------|-------------|-----------------------|
| 1 Lluta      |             | Alcerreca             |
| 2 Lluta      |             | Tocontasi             |
| 3 San José   |             | Antes Bocatoma        |
| 4 Vitor      | Qda. Vitor  | Qda. Vitor            |
| 5 Camarones  |             | Camarones             |
| 6 Tana       | Qda. Camiña | Qda. Camiña           |
| 7 Tana       | Qda. Camiña | Altusa                |
| 8 Tarapacá   |             | Mina San Juan         |
| 9 Chacarilla |             | Salado                |
| 10 Loa       | San Pedro   | San Pedro             |
| 11 Loa       | San Pedro   | San Pedro (Inacaliri) |
| 12 Loa       |             | Desp. Junta           |
| 13 Loa       |             | Lequena               |

However, the data at Peñablanca of Collacagua River were not used in this analysis. Because some portion of the river flow infiltrates into underground before reaching Peñablanca station since the station is located on the alluvial deposits. Furthermore, some river water bypasses the station at a flood time. The station does not catch the whole run-off of the upstream basin. The calculated run-off coefficient is considered not correct, too small compared to the corresponding rainfall depth.

The relationship between rainfall and run-off coefficient is established as shown in Fig. A, 5.1. It is expressed by a linear equation as follows.

$$R = af + b$$

where  $R$  = Average total rainfall in a year (mm/year),  
 $f$  = Runoff coefficient,  
 $a, b$  = constant

Parameter  $a$  and  $b$  are calculated by Least Square Method using rainfall and runoff coefficient as values of samples. The result is shown below.

$$R = 1,192.39 f + 38.960$$

where Correlation coefficient ( $r$ ) = 0.9778

From this equation, average yearly flow rate in seven (7) tributaries in Pampa del Tamarugal including Aroma, Tarapacá, Quipisca, Sagasca (Juan Morales), Quisma (Pica), Chacarilla and Ramada Rivers can be estimated as shown in Table A, 5.1.

Calculated yearly average flow rate of the rivers in Pampa del Tamarugal are as follow;

| <u>River</u> | <u>Flow Rate (m<sup>3</sup>/s)</u> |
|--------------|------------------------------------|
| Aroma        | 0.310                              |
| Quipisca     | 0.089                              |
| Sagasca      | 0.072                              |
| Quisma       | 0.021                              |
| Chacarilla   | 0.159                              |
| Ramada       | 0.007                              |
| Tarapaca     | 0.318                              |
| <u>Total</u> | 0.976                              |

The total flow rate of the basin was estimated by Chile University as well in 1988 (Refer to Modelo de Simulacion Hidrogeologico de la Pampa del Tamarugal Informe, 1988, Universidad de Chile). It is 1.002 m<sup>3</sup>/s, about 2.6 % different from the calculation of this study.

The surface run-off from the whole area of Salar del Huasco Basin is also estimated by using the above equation as shown in Table A, 5.1. The yearly average run-off is calculated at 0.809 m<sup>3</sup>/s.

Table A, S.1 (1) Calculated Runoff in Pampa del Tamarugal and Salar de Huasco Basin  
 <Escorrentias Calculadas en la Cuenca de la  
 Cuenca del Pampa del Tamarugal y Salar de Huasco>  
 (Liner Equation of Average Rainfall and Runoff Coefficient :  $R = 1,192.39 f + 38.960$ )
